VOQUEZNA TRIPLE PAK and VOQUEZNA DUAL PAK are co-packaged for oral use and contain:

- Amoxicillin 500 mg (capsules)
- Clarithromycin 500 mg (capsules)
- Vonoprazan 40 mg (capsules)

VOQUEZNA TRIPLE PAK is indicated for the treatment of Helicobacter pylori infection in adults. It is recommended for use in the treatment of H. pylori infection in adults, 12 hours apart, with or without food, for 14 days.

VOQUEZNA DUAL PAK contains amoxicillin 500 mg and either clarithromycin 500 mg or lansoprazole 30 mg or pantoprazole 40 mg. It is indicated for the treatment of H. pylori infection in adults, 12 hours apart, with or without food, for 14 days.

Additional Warnings and Precautions:

- Hypersensitivity Reactions: Serious and occasionally fatal reactions (e.g., anaphylaxis) have been reported with components of VOQUEZNA TRIPLE PAK and VOQUEZNA DUAL PAK. If hypersensitivity reactions occur, discontinue VOQUEZNA TRIPLE PAK or VOQUEZNA DUAL PAK and institute immediate therapy (e.g., anaphylaxis management).
- Severe Cutaneous Adverse Reactions (SCAR): Discontinue VOQUEZNA TRIPLE PAK or VOQUEZNA DUAL PAK at the first signs or symptoms of SCAR or other signs of hypersensitivity and consider further evaluation.
- Clostridioides difficile-associated diarrhea (CDAD): Evaluate for diarrhea occurs with VOQUEZNA TRIPLE PAK and VOQUEZNA DUAL PAK.

To reduce the development of drug-resistant bacteria and maintain the effectiveness of VOQUEZNA TRIPLE PAK and VOQUEZNA DUAL PAK and other antibacterial drugs, VOQUEZNA TRIPLE PAK and VOQUEZNA DUAL PAK should be used only to treat or prevent infections that are proven or strongly suspected to be caused by bacteria. (1.2)

6.1 Clinical Trials Experience

INDICATIONS AND USAGE

VOQUEZNA TRIPLE PAK, a co-packaged product containing vonoprazan, a potassium-competitive acid blocker (PCAB), amoxicillin, a penicillin class antibiotic, and clarithromycin, a macrolide antimicrobial, is indicated for the treatment of Helicobacter pylori infection in adults. (1.1)

VOQUEZNA DUAL PAK, a co-packaged product containing vonoprazan, a PCAB, and amoxicillin, a penicillin class antibiotic, is indicated for the treatment of Helicobacter pylori infection in adults. (1.1)

The recommended dosage regimens for voqueza triple pak are

- VOQUEZNA TRIPLE PAK: The recommended dosage regimen is vonoprazan 20 mg plus amoxicillin 1,000 mg plus clarithromycin 500 mg, each given twice daily (morning and evening), 12 hours apart, with or without food, for 14 days. (2.1)
- VOQUEZNA DUAL PAK: The recommended dosage regimen is vonoprazan 20 mg twice daily (morning and evening) plus amoxicillin 1,000 mg, three times a day (morning, mid-day, and evening), with or without food, for 14 days. (2.2)

DOSAGE FORMS AND STRENGTHS

VOQUEZNA TRIPLE PAK: Carton of 14 daily administration packs for morning and evening dosing, each containing the following three drug products (3.1):

- Tablets: Vonoprazan 20 mg
- Tablets: Clarithromycin 500 mg
- Capsules: Amoxicillin 500 mg

VOQUEZNA DUAL PAK: Carton of 14 daily administration packs for morning, mid-day and evening dosing, each containing the following two drug products (3.2):

- Tablets: Vonoprazan 20 mg
- Capsules: Amoxicillin 500 mg

CONTRAINDICATIONS

VOQUEZNA TRIPLE PAK and VOQUEZNA DUAL PAK:

- Known hypersensitivity to vonoprazan, amoxicillin or any other beta-lactams, clarithromycin or any other macrolide antimicrobial or any component of VOQUEZNA TRIPLE PAK. (4.1)
- Known hypersensitivity to vonoprazan, amoxicillin or any other beta-lactams or any component of VOQUEZNA DUAL PAK. (4.1)
- Ritilivirine-containing products. (4.1)
- VOQUEZNA TRIPLE PAK Due to the Clarithromycin Component:
  - Pimozide. (4.2)
  - Lomitapide, lovastatin, and simvastatin. (4.2)
  - Ergot alkaloids (ergotamine or dihydroergotamine). (4.2)
  - Colchicine in renal or hepatic impairment. (4.2)
  - History of cholestatic jaundice/hepatic dysfunction with use of clarithromycin. (4.2)

Revised: 5/2022
4.2. Additional Contraindications to VOQUEZNA TRIPLE PAK Due to the Hypersensitivity Reactions
VOQUEZNA TRIPLE PAK and VOQUEZNA DUAL PAK are contraindicated in patients with a known hypersensitivity to any component of VOQUEZNA TRIPLE PAK: vonoprazan, amoxicillin (or other β-lactam antibacterials, e.g., penicillins and cephalosporins) or clarithromycin (or other macrolide antimicrobial drugs, e.g., erythromycin) or VOQUEZNA DUAL PAK: vonoprazan or amoxicillin (or other β-lactam antibacterials, e.g., penicillins and cephalosporins) [see Warnings and Precautions (5.1)]. Rilpine-containing Products
VOQUEZNA TRIPLE PAK and VOQUEZNA DUAL PAK are contraindicated with rilpine-containing products [see Drug Interactions (7)].

4.2. Additional Contraindications to VOQUEZNA TRIPLE PAK Due to the Clarithromycin Component
Serious Adverse Reactions/Risks Due to Drug Interactions
Because of the clarithromycin component, VOQUEZNA TRIPLE PAK is contraindicated with concomitant use of:
- Pimozide: There have been postmarketing reports of drug interactions when clarithromycin is co-administered with pimozide, resulting in cardiac arrhythmias (QT prolongation, ventricular tachycardia, ventricular fibrillation, and torsades de pointes) most likely due to inhibition of metabolism of these drugs by clarithromycin. Fatalities have been reported [see Warnings and Precautions (5.2) and Drug Interactions (7)].
- Lipid-lowering Agents: Lomitapide, simvastatin, and lovastatin [see Warnings and Precautions (5.2) and Drug Interactions (7)].
- Ergot Alkaloids: Ergotamine or dihydroergotamine [see Drug Interactions (7)].
- Colchicine in patients with renal or hepatic impairment [see Warnings and Precautions (5.2) and Drug Interactions (7)].

Cholestatic Jaundice/Hepatic Dysfunction
VOQUEZNA TRIPLE PAK is contraindicated in patients with a history of cholestatic jaundice or hepatic dysfunction associated with prior use of clarithromycin.

5. WARNINGS AND PRECAUTIONS
5.1. Warnings and Precautions for VOQUEZNA TRIPLE PAK and VOQUEZNA DUAL PAK
Hypersensitivity Reactions
Serious and occasionally fatal hypersensitivity reactions (e.g., anaphylaxis, anaphylactic shock, rash, erythroema multiforme, and Henoch–Schonlein purpura) have been reported with components of VOQUEZNA TRIPLE PAK and VOQUEZNA DUAL PAK [see Contraindications (4.1)].

Before initiating therapy with VOQUEZNA TRIPLE PAK or VOQUEZNA DUAL PAK careful inquiry should be made regarding previous hypersensitivity reactions to penicillins, cephalosporins, macrolide antibacterial drugs or other allergens. Discontinue VOQUEZNA TRIPLE PAK or VOQUEZNA DUAL PAK immediately and institute appropriate treatment if hypersensitivity occurs.

Severe Cutaneous Adverse Reactions
Severe cutaneous adverse reactions (SCAR), including Stevens-Johnson syndrome (SJS) and toxic epidermal necrolysis (TEN) have been reported with the components of VOQUEZNA TRIPLE PAK: vonoprazan, amoxicillin and clarithromycin and VOQUEZNA DUAL PAK: vonoprazan and amoxicillin [see Adverse Reactions (6.2)]. In addition, drug reaction with eosinophilia and systemic symptoms (DRESS), and acute generalized exanthematous pustulosis (AGEP) have been reported with amoxicillin and clarithromycin.

Discontinue VOQUEZNA TRIPLE PAK or VOQUEZNA DUAL PAK at the first signs or symptoms of SCAR or other signs of hypersensitivity and consider further evaluation.

Clostridioides difficile-Associated Diarrhea
Clostridioides difficile-associated diarrhea (CDAD) has been reported with use of acid suppressing therapies and nearly all antibacterial agents, including amoxicillin (component of VOQUEZNA DUAL PAK and TRIPLE PAK) and clarithromycin (component of VOQUEZNA TRIPLE PAK), and may range in severity from mild diarrhea to fatal colitis. Treatment with antibacterial agents alters the normal flora of the colon leading to overgrowth of Clostridioides difficile (C. difficile).

C. difficile produces toxins A and B which contribute to the development of CDAD. Hyperosmoty-producing strains of C. difficile cause increased morbidity and mortality, as these infections can be refractory to antimicrobial therapy and may require colectomy. CDAD must be considered in all patients who present with diarrhea following antibacterial use. Careful medical history is necessary since CDAD has been reported to occur over two months after the administration of antibacterial agents.

If CDAD is confirmed, VOQUEZNA TRIPLE PAK and VOQUEZNA DUAL PAK should be discontinued. Appropriate fluid and electrolyte management, protein supplementation, antibacterial treatment of C. difficile, and surgical evaluation should be instituted as clinically indicated.

Rash in Patients with Mononucleosis
A high percentage of patients with mononucleosis who receive amoxicillin (a component of VOQUEZNA TRIPLE PAK and VOQUEZNA DUAL PAK) develop an erythematous skin rash. Avoid use of VOQUEZNA TRIPLE PAK and VOQUEZNA DUAL PAK in patients with mononucleosis.

Interactions with Diagnostic Investigations for Neuroendocrine Tumors
Serum chromogranin A (CgA) levels increase secondary to drug-induced decreases in gastric acidity. The increased CgA level may cause false positive results in diagnostic investigations for neuroendocrine tumors. Assess CgA levels at least 14 days after VOQUEZNA TRIPLE PAK and VOQUEZNA DUAL PAK treatment and consider repeating the test if initial CgA levels are high [see Drug Interactions (7)].

Development of Drug-Resistant Bacteria
Prescribing VOQUEZNA TRIPLE PAK or VOQUEZNA DUAL PAK in the absence of a proven or strongly suspected bacterial infection or prophylactic indication is unlikely to provide benefit to the patient, and increases the risk of the development of drug-resistant bacteria.

5.2. Additional Warnings and Precautions for VOQUEZNA TRIPLE PAK Due to the Clarithromycin Component
QT Prolongation
Clarithromycin (a component of VOQUEZNA TRIPLE PAK) has been associated with prolongation of the QT interval and infrequent cases of arrhythmia. Cases of torsades de pointes and other cases of ventricular arrhythmia have been reported during postmarketing surveillance in patients receiving clarithromycin. Fatalities have been reported.

Avoid VOQUEZNA TRIPLE PAK in the following patients:
- Patients with known prolongation of QT interval, ventricular cardiac arrhythmia, including torsades de pointes.
- Patients receiving drugs known to prolong the QT interval (e.g., pimozide).
- Patients with ongoing proarrhythmic conditions such as uncorrected hypokalemia or hypomagnesemia, clinically significant bradycardia and in patients receiving Class IA (e.g., quinidine, procainamide, disopyramide) or Class III ( dofetilide, amiodarone, sotalol) antiarrhythmic agents.

Elderly patients may be more susceptible to drug-associated effects on the QT interval [see Use in Specific Populations (8.5)].
Hepatotoxicity
Hepatic dysfunction, including increased liver enzymes, and hepatocellular and/or cholestatic hepatitis, with or without jaundice, has been reported with clarithromycin (a component of VOQUEZNA TRIPLE PAK). This hepatic dysfunction may be severe and is usually reversible. In some instances, hepatic failure with fatal outcome has been reported and generally has been associated with serious underlying diseases and/or concomitant medications. Symptoms of hepatitis can include anorexia, jaundice, dark urine, pruritus, or tender abdomen.

Discontinue VOQUEZNA TRIPLE PAK immediately if signs and symptoms of hepatitis occur.

Serious Adverse Reactions Due to Concomitant Use of Clarithromycin with Other Drugs

Serious adverse reactions have been reported in patients taking clarithromycin (a component of VOQUEZNA TRIPLE PAK) concomitantly with CYP3A4 substrates. These include colchicine toxicity with colchicine; markedly increased transaminases with lomitapide; rhabdomyolysis with simvastatin, lovastatin, and atorvastatin; hypoglycemia and cardiac arrhythmias (e.g., torsades de pointes) with disopyramide; and hypotenison and acute kidney injury with calcium channel blockers metabolized by CYP3A4 (e.g., verapamil, amiodipine, diltiazem, nifedipine). Most reports of acute kidney injury with calcium channel blockers metabolized by CYP3A4 involved elderly patients 65 years of age or older [see Contraindications (4.2) and Drug Interactions (7)].

Colchicine
Life-threatening and fatal drug interactions have been reported in patients treated with clarithromycin (a component of VOQUEZNA TRIPLE PAK) and colchicine. If co-administration of VOQUEZNA TRIPLE PAK and colchicine is necessary in patients with normal renal and hepatic function, reduce the dose of colchicine. Monitor patients for clinical symptoms of colchicine toxicity. Concomitant administration of VOQUEZNA TRIPLE PAK and colchicine is contraindicated in patients with renal or hepatic impairment [see Contraindications (4.2) and Drug Interactions (7)].

Lomitapide
Concomitant use of VOQUEZNA TRIPLE PAK with lomitapide may increase the risk of elevation in transaminases due to the clarithromycin component. Concomitant use of VOQUEZNA TRIPLE PAK with lomitapide is contraindicated [see Contraindications (4.2) and Drug Interactions (7)]. If treatment with VOQUEZNA TRIPLE PAK cannot be avoided, therapy with lomitapide must be suspended during the course of treatment.

HMG-CoA Reductase Inhibitors (statins)
Concomitant use of VOQUEZNA TRIPLE PAK with lovastatin or simvastatin may increase these drug's plasma concentrations due to the clarithromycin component, which may increase the risk of myopathy, including rhabdomyolysis. Cases of rhabdomyolysis have been reported in patients treated concomitantly with clarithromycin (a component of VOQUEZNA TRIPLE PAK) and lovastatin or simvastatin. Concomitant use of VOQUEZNA TRIPLE PAK with lovastatin or simvastatin is contraindicated [see Contraindications (4.2)]. If treatment with VOQUEZNA TRIPLE PAK cannot be avoided, therapy with lovastatin or simvastatin must be suspended during the course of treatment. Exercise caution when prescribing VOQUEZNA TRIPLE PAK with atorvastatin or pravastatin [see Drug Interactions (7)].

Hypoglycemic Agents/Insulin
Concomitant use of VOQUEZNA TRIPLE PAK, and hypoglycemic agents (such as nateglinide, pioglitazone, repaglinide and rosiglitazone) and/or insulin can result in significant hypoglycemia due to the clarithromycin component. Carefully monitor glucose levels when these drugs are used concomitantly with VOQUEZNA TRIPLE PAK [see Drug Interactions (7)].

Quetiapine
Concomitant use of VOQUEZNA TRIPLE PAK with quetiapine could result in somnolence, orthostatic hypotension, altered state of consciousness, neuroleptic malignant syndrome, and QT prolongation due to the clarithromycin component. Refer to quetiapine prescribing information for recommended dosage reduction if co-administered with VOQUEZNA TRIPLE PAK [see Drug Interactions (7)].

Warfarin
There is a risk of serious hemorrhage and significant elevations in the international normalized ratio (INR) and prothrombin time when clarithromycin (a component of VOQUEZNA TRIPLE PAK) is used concomitantly with warfarin. Monitor INR and prothrombin times frequently when warfarin is used concomitantly with VOQUEZNA TRIPLE PAK.

Benzodiazepines
Increased sedation and prolongation of sedation have been reported with concomitant administration when clarithromycin (a component of VOQUEZNA TRIPLE PAK), and triazolobenzodiazepines, such as triazolam and midazolam. Closely monitor patients for signs or symptoms of increased or prolonged central nervous system effects when benzodiazepines such as atrazolam or midazolam are used concomitantly with VOQUEZNA TRIPLE PAK [see Drug Interactions (7)].

Embryo-Fetal Toxicity with Use of VOQUEZNA TRIPLE PAK

Based on findings from animal studies and human observational studies in pregnant women with use of clarithromycin, VOQUEZNA TRIPLE PAK is not recommended for use in pregnant women. Pregnancy occurs while the patient is taking this drug, advise the patient of the potential risk to the fetus. Clarithromycin demonstrated adverse effects on pregnancy outcome and/or embryo fetal development, in pregnant animals administered oral clarithromycin. Observational studies in pregnant women also demonstrated adverse effects on pregnancy outcomes, including an increased risk of miscarriage and in some studies an increased incidence of fetal malformations [see Use in Specific Populations (8.1)].

Exacerbation of Myasthenia Gravis
Exacerbation of symptoms of myasthenia gravis and new onset of symptoms of myasthenic syndrome has been reported in patients receiving clarithromycin therapy (a component of VOQUEZNA TRIPLE PAK). Monitor patients for symptoms.

6. ADVERSE REACTIONS

The following serious adverse reactions are described below and elsewhere in labeling:

- Hypersensitivity Reactions [see Warnings and Precautions (5.1)]
- Clostridioides difficile-Associated Diarrhea [see Warnings and Precautions (5.1)]
- QT Prolongation [see Warnings and Precautions (5.2)]
- Hepatotoxicity [see Warnings and Precautions (5.2)]
- Serious Adverse Reactions Due to Concomitant Use with Other Drugs [see Warnings and Precautions (5.2)]
- Exacerbation of Myasthenia Gravis [see Warnings and Precautions (5.2)]

6.1. Clinical Trials Experience

Because clinical trials are conducted under widely varying conditions, adverse reaction rates observed in the clinical trials of a drug cannot be directly compared to rates in the clinical trials of another drug and may not reflect the rates observed in practice.

Adverse Reactions with VOQUEZNA TRIPLE PAK and VOQUEZNA DUAL PAK

The safety of VOQUEZNA TRIPLE PAK was evaluated in 675 adult patients (aged 20 to 82 years) in clinical trials in the United States, Europe and Japan and VOQUEZNA DUAL PAK was evaluated in 348 adult patients (aged 20 to 80 years) in a clinical trial in the United States and Europe. All the patients were screened and found to be positive for H. pylori infection.

The safety of VOQUEZNA TRIPLE PAK and VOQUEZNA DUAL PAK was evaluated in a randomized, controlled, double-blind triple therapy/open-label dual therapy study conducted in the United States and Europe in treatment-naive H. pylori-positive adult patients. Patients were randomized 1:1:1 to vonoprazan 20 mg twice daily plus amoxicillin 1,000 mg twice daily plus clarithromycin 500 mg twice daily (VOQUEZNA TRIPLE PAK) or vonoprazan 20 mg twice daily plus amoxicillin 1,000 mg three times daily (VOQUEZNA DUAL PAK) or lansoprazole 30 mg twice daily plus amoxicillin 1,000 mg twice daily plus clarithromycin 500 mg twice daily (LAC) administered for 14 consecutive days. A total of 346 patients received VOQUEZNA TRIPLE PAK in the study, 348 received VOQUEZNA DUAL PAK and 345 received LAC. These patients had a mean age of 51 years (range 20 to 87 years); 82.2% were female, 89.3% were White, 7.4% Black or African American, 1.5% were Asian and 1.8% were others with 72.5% non-Hispanic or Latino.

Adverse Reactions Leading to Discontinuation

Treatment discontinuation due to an adverse reaction occurred in 2.3% (8/346) of the VOQUEZNA TRIPLE PAK-treated patients, 0.9% (3/348) of the VOQUEZNA DUAL PAK-treated patients and 1.2% (4/345) of the LAC-treated patients. The most common adverse reactions leading to discontinuation of VOQUEZNA TRIPLE PAK were diarrhea (0.6%) and hypertension (0.6%) and the most common adverse reaction leading to discontinuation of VOQUEZNA DUAL PAK was rash (0.6%).

Most Common Adverse Reactions

The adverse reactions occurring in ≥2% of patients are described in Table 1.

a Dysgeusia also includes taste disorder.

b Vulpovaginal candidiasis includes: urogenital infection fungal, vulvovaginal candidiasis, vulvovaginal mycotic infection, vulvovaginal pruritus, pruritus genital, genital infection fungal.

c Abdominal pain includes: abdominal discomfort, abdominal pain, abdominal pain lower, abdominal pain upper.

d Hypertension also includes blood pressure increased.

This study was not designed to evaluate meaningful comparisons of the incidence of adverse reactions in the VOQUEZNA DUAL PAK, VOQUEZNA TRIPLE PAK, and LAC treatment groups.
Other Adverse Reactions
Other adverse reactions occurring in <2% of patients with VOQUEZNA TRIPLE PAK or VOQUEZNA DUAL PAK are listed below by body system:

Blood and lymphatic system disorders: anemia, leukocytosis, leukopenia, neutropenia.
Cardiac disorders: QT prolongation, tachycardia.
Eye disorders: orbital edema.
Gastrointestinal disorders: abdominal distension, constipation, dry mouth, duodenal polyph, duodenal ulcer, dyspepsia, flatulence, gastric ulcer, gastroesophageal reflux disease, hematochezia, large intestine polyph, nausea, rectal polyph, stomatitis, tongue discomfort, vomiting.
General disorders and administration site conditions: fatigue, pyrexia.
Immune system disorders: drug hypersensitivity.
Infections and infestations: fungal infection, gastrointestinal viral infection, oral fungal infection, pneumonia, upper respiratory tract infection.
Renal and urinary disorders: renal hypocitruria, tubulointerstitial nephritis.
Reproductive system and breast disorders: vaginal discharge.
Respiratory, thoracic and mediastinal disorders: cough, nasal polyps, oropharyngeal pain.
Skin and subcutaneous tissue disorders: dermatitis, dry skin, rash.

6.2. Postmarketing Experience with Components of VOQUEZNA TRIPLE PAK and VOQUEZNA DUAL PAK
The following adverse reactions have been identified during post-approval use of vonoprazan (outside of the United States), amoxicillin or clarithromycin (all used separately). Because these reactions are reported voluntarily from a population of uncertain size, it is not always possible to reliably estimate their frequency or establish a causal relationship to drug exposure.

Vonoprazan

Immune system disorders: anaphylactic shock, urticaria, drug eruption [see Contraindications (4.1)].
Hepatobiliary disorders: hepatic injury, hepatic failure, jaundice.
Skin and subcutaneous tissue disorders: erythema multiforme, SJS, TEN [see Warnings and Precautions (5.1)].

Amoxicillin

Infections and infestations: mucocutaneous candidiasis.
Gastrointestinal: black hairy tongue, and hemorrhagic/pseudomembranous colitis. Onset of pseudomembranous colitis symptoms may occur during or after antibacterial treatment [see Warnings and Precautions (5.1)].
Hypersensitivity reactions: anaphylaxis [see Contraindications (4.1), Warnings and Precautions (5.1)].
Serum sickness–like reactions, erythematous maculopapular rash, angioedema.

7. DRUG INTERACTIONS
Collated drug interaction information for the individual components in VOQUEZNA TRIPLE PAK and VOQUEZNA DUAL PAK is summarized below. Drug interaction studies with VOQUEZNA TRIPLE PAK or VOQUEZNA DUAL PAK have not been conducted. These recommendations are based on either drug interaction trials or predicted interactions due to the expected magnitude of interaction and potential for serious adverse reactions or loss of efficacy [see Clinical Pharmacology (12.3)].

Clarithromycin (a component of VOQUEZNA TRIPLE PAK) is a strong CYP3A inhibitor. Concomitant use of VOQUEZNA TRIPLE PAK with a drug(s) primarily metabolized by CYP3A may cause elevations in CYP3A substrate drug’s concentrations that could increase or prolong both therapeutic and adverse effects of the concomitant drug.

### Table 4: Effects of VOQUEZNA TRIPLE PAK on Other Drugs

#### Clinical Effect
- Clarithromycin is a substrate and strong inhibitor of CYP3A4. Clarithromycin increases exposure of CYP3A substrates [see Clinical Pharmacology (12.3)], which may increase the risk of adverse reactions related to these substrates [see Warnings and Precautions (5.2)]. Strong or moderate CYP3A inducers may decrease exposure of clarithromycin. There have been spontaneous or published reports of CYP3A based interactions of clarithromycin with anti-HIV agents (e.g., Nelfinavir, amoxicillin, and/or clarithromycin were conducted.

#### Prevention or Management
- Use VOQUEZNA TRIPLE PAK with caution.

#### 8. USE IN SPECIFIC POPULATIONS

#### 8.1. Pregnancy

**Risk Summary**
- VOQUEZNA TRIPLE PAK
  - Based on findings from animal studies and observational studies in pregnant women with use of clarithromycin, use of VOQUEZNA TRIPLE PAK is not recommended in pregnant women except in clinical circumstances where no alternative therapy is appropriate. There are no adequate and well-controlled studies of VOQUEZNA TRIPLE PAK in pregnant women to evaluate for drug-associated risks of major birth defects, miscarriage, or other adverse maternal or fetal outcomes. If VOQUEZNA TRIPLE PAK is used during pregnancy, advise pregnant women of the potential risk to a fetus. No reproductive and developmental toxicity studies with the combination of vonoprazan, amoxicillin, and/or clarithromycin were conducted.

**VOQUEZNA DUAL PAK**
- There are no adequate and well-controlled studies of VOQUEZNA DUAL PAK in pregnant women to evaluate for drug-associated risks of major birth defects, miscarriage, or other adverse maternal or fetal outcomes.

**Individual Components of VOQUEZNA TRIPLE PAK and VOQUEZNA DUAL PAK**
- Clarithromycin:
  - Published observational studies in pregnant women have demonstrated adverse effects on pregnancy outcomes, including an increased risk of miscarriage and in some studies an increased incidence of fetal malformations [see Data]. In animal reproduction studies, administration of oral clarithromycin to pregnant mice, rats, rabbits, and monkeys during the period of organogenesis produced malformations in rats (cardiovascular anomalies) and mice (cleft palate) at clinically relevant doses. Fetal effects in mice, rats, and monkeys (e.g., reduced fetal survival, body weight, body weight gain) and implantation losses in rabbits were generally considered to be secondary to maternal toxicity [see Data].
Vonoprazan:
Available data from pharmacovigilance reports with vonoprazan use in pregnant women are not sufficient to evaluate for a drug-associated risk for major birth defects, miscarriage or other adverse maternal or fetal outcomes. In pregnant rats, no adverse effects were noted after oral administration of vonoprazan during organogenesis at approximately 27 times the maximum recommended human dose (MRHD) based on AUC exposure comparisons. In a pre- and postnatal development (PPND) study, pups from dams orally administered vonoprazan during organogenesis and through lactation, exhibited liver discoloration, which in fetal mechanistic dosing studies was associated with necrosis, fibrosis, hemorrhage and at a dose approximately 22 times the MRHD based on AUC comparisons which were likely attributable to exposure during lactation [see Use in Specific Populations (8.2)]. These effects were not observed at the next lower dose in this study, which was approximately equal to the MRHD based on AUC comparison, however they were seen at clinically relevant exposures in dose range finding studies in rats (see Data).

Amoxicillin:
Available data from published epidemiologic studies and pharmacovigilance case reports over several decades with amoxicillin use have not established drug-associated risks of major birth defects, miscarriage, or other adverse maternal or fetal outcomes. Reproduction studies with amoxicillin have been performed in mice and rats (5 and 10 times the human dose 2 g human dose for mice and rats, respectively, 3 and 6 times the 3 g human dose for mice and rats, respectively). There was no evidence of harm to the fetus due to amoxicillin.

The estimated background risks of major birth defects and miscarriage for the indicated population are unknown. In clinical trials, amoxicillin has not been associated with risk of birth defect, loss, or other adverse outcomes. In the US general population, the estimated background risk of major birth defects and miscarriage in clinically recognized pregnancies is 2% to 4% and 15% to 20%, respectively.

Available data from published epidemiologic studies and pharmacovigilance case reports [see Clinical Pharmacology (12.3)]. The clinical relevance of the liver findings is uncertain.

Exposure margins from vonoprazan between the animal and clinical studies for vonoprazan, amoxicillin and clarithromycin used in combination may be lower due to increased vonoprazan exposure from concomitant use with clarithromycin in patients [see Clinical Pharmacology (12.3)].

AUC:
Available data from published epidemiologic studies and pharmacovigilance case reports over several decades with amoxicillin use have not established drug-associated risks of major birth defects, miscarriage, or other adverse maternal or fetal outcomes. Available data have methodologic limitations, including small sample size, under-capture of non-live births, exposure misclassification and inconsistent comparator groups.

Animal Data:
Clarithromycin:
Animal reproduction studies were conducted in mice, rats, rabbits, and monkeys with oral and intravenously administered clarithromycin. In pregnant mice, clarithromycin was administered during organogenesis (gestation day [GD] 6 to 15) at oral doses of 15, 60, 250, 500, or 1000 mg/kg/day. Reduced body weight observed in dams at 1000 mg/kg/day (3 times the MRHD based on BSA comparison) resulted in reduced survival and body weight of the fetuses at ≥ 500 mg/kg/day, increases in the incidence of post-implantation loss and cleft palate in the fetuses were observed. No adverse developmental effects were observed in mice at ≤ 250 mg/kg/day (≥ 1 times MRHD based on BSA comparison).

In pregnant Sprague Dawley rats, clarithromycin was administered during organogenesis (GD 6 to 15) at oral doses of 15, 50, or 150 mg/kg/day. Reductions in body weight and food consumption was observed in dams at 150 mg/kg/day. Increased resorptions and reduced body weight of the fetuses at this dose were considered secondary to maternal toxicity. Additionally, at 150 mg/kg/day (1 times MRHD based on BSA comparison), a low incidence of cardiovascular anomalies (complete situs inversus, undivided truncus, IV septal defect) was observed in the fetuses. Clarithromycin did not cause adverse developmental effects in rats at 50 mg/kg/day (0.3 times MRHD based on BSA comparison) intravenous dosing of clarithromycin during organogenesis in rats (GD 6 to 15) at 15, 50, or 160 mg/kg/day was associated with maternal toxicity (reduced body weight, body-weight gain, and food consumption) at 160 mg/kg/day but no evidence of adverse developmental effects at any dose (≤ 1 times MRHD based on BSA comparison).

In pregnant Wistar rats, clarithromycin was administered during organogenesis (GD 7 to 17) at oral doses of 10, 40, or 160 mg/kg/day. Reduced body weight and food consumption were observed in dams at 160 mg/kg/day but there was no evidence of adverse developmental effects at any dose (≤ 1 times MRHD based on surface BSA comparison).

In pregnant rabbits, clarithromycin administered during organogenesis (GD 6 to 18) at oral doses of 10, 35, or 125 mg/kg/day resulted in reduced maternal food consumption and decreased body weight at the highest dose, with no evidence of any adverse developmental effects at any dose (2 times MRHD based on BSA comparison) in rabbits (see Data). Intravenously administered clarithromycin to pregnant rabbits during organogenesis (GD 6 to 18) in rabbits at 20, 40, 80, or 160 mg/kg/day (≥ 0.3 times MRHD based on BSA comparison) resulted in maternal toxicity and implantation losses at all doses.

In pregnant monkeys, clarithromycin was administered (GD 20 to 50) at oral doses of 35 or 70 mg/kg/day. Dose-dependent emesis, poor appetite, fecal changes, and reduced body weight were observed in dams at all doses (≥ 0.5 times MRHD based on BSA comparison). Growth retardation in 1 fetus at 70 mg/kg/day was considered secondary to maternal toxicity. There was no evidence of primary drug related adverse developmental effects at any dose tested.

In a reproductive toxicology study in rats administered oral clarithromycin late in gestation (GD 17 to post-natal day 21) at doses of 10, 40, or 160 mg/kg/day (≤ 1 times MRHD based on BSA comparison), reductions in maternal body weight and food consumption were observed at 160 mg/kg/day. Reduced body weight gain observed in offspring at 160 mg/kg/day was considered secondary to maternal toxicity. No adverse developmental effects were observed with clarithromycin at any dose tested.

Vonoprazan:
Pregnant rats were orally administered vonoprazan at doses of 30, 100 or 300 mg/kg/day (7.27, 130 times the MRHD based on AUC comparison at the same doses from unmetabolized vonoprazan fraction based on single study in organogenesis). No embryo-fetal lethality was observed but decreased fetal body weight was observed in the highest dose group. Fetal abnormalities were limited to the 300 mg/kg/day dose group and included ventricular septal defect and mal-positioned subclavian artery in fetuses in a majority (15/19) of litters, as well as tail abnormalities, and small anal opening. No adverse embryo-fetal effects were observed at the 100 mg/kg/day.

Pregnant rabbits were orally administered vonoprazan at doses of 3, 10, or 30 mg/kg/day (0.04, 1.5, 10 times the MRHD based on AUC comparison) from GD 6 to lactation day (LD) 21. Decreased body weight gain and food consumption were present in dams at the highest dose during lactation. Decreased body weight gain compared to controls was observed in offspring from dams in the high dose group. Liver discoloration occurred in offspring from the high dose group at LD 4 but was not present in animals examined after weaning. Similarly, in dose range finding studies in rats and follow-up mechanistic animal studies, the liver discoloration was observed and characterized as necrosis, fibrosis and hemorrhage at equal to or greater than clinically relevant exposures based on AUC comparisons. The mechanistic studies further demonstrated the effect was likely attributable to vonoprazan exposure during lactation [see Use in Specific Populations (8.2)]. The clinical relevance of the liver findings is uncertain.

Exposure margins from vonoprazan between the animal and clinical studies for vonoprazan, amoxicillin and clarithromycin used in combination may be lower due to increased vonoprazan exposure from concomitant use with clarithromycin in patients [see Clinical Pharmacology (12.3)].

Risk Summary
There are no data regarding the presence of vonoprazan in human milk, the effects on the breastfed infant or the effects on milk production. Vonoprazan and its metabolites are present in rat milk. Liver injury occurred in offspring from pregnant and lactating rats administered oral vonoprazan at AUC exposures approximately equal to and greater than the MRHD (see Data). When a drug is present in animal milk, it is likely that the drug will be present in human milk. Because of the potential risk of adverse liver effects shown in animal studies with vonoprazan, a woman should pump and discard human milk for the duration of VOQUEZNA TRIPLE PAK or VOQUEZNA DUAL PAK therapy, and for 2 days after therapy ends, and feed her infant stored human milk (collected prior to therapy) or formula.

Based on data from a published lactation study, clarithromycin and its active metabolite 14-OH clarithromycin are present in human milk at less than 2% of the maternal weight-adjusted dose (see Data). In a separate observational study of lactating women exposed to clarithromycin, reported adverse effects on breast-fed children (rash, diarrhea, loss of appetite, somnolence) were comparable to amoxicillin. No data are available to assess the effects of clarithromycin or 14-OH clarithromycin on milk production.

Data from published clinical lactation study reports that amoxicillin is present in human milk. There are no data on the effects of amoxicillin on milk production.
8.3. Females and Males of Reproductive Potential
Infertility

Males
Clarithromycin:
Based on animal fertility study findings for clarithromycin, VOQUEZNA TRIPLE PAK may impair fertility and may harm offspring. 

8.4. Pediatric Use
Safety and effectiveness of VOQUEZNA TRIPLE PAK or VOQUEZNA DUAL PAK in pediatric patients have not been established.

8.5. Geriatric Use
Geriatric Use for the Individual Components of VOQUEZNA TRIPLE PAK and VOQUEZNA DUAL PAK
Amoxicillin and Clarithromycin
Amoxicillin and clarithromycin are known to be substantially excreted by the kidney, and the risk of adverse reactions to these drugs may be greater in patients with impaired renal function and it may be useful to monitor renal function [see Use in Specific Populations (8.6)].

Vonoprazan:
There were 218 patients aged 65 years and older in the clinical study of VOQUEZNA TRIPLE PAK and VOQUEZNA DUAL PAK for the treatment of H. pylori infection [see Clinical Studies (14)]. Of the total number of vonoprazan-treated subjects (N=694), there were 153 (22.0%) patients aged 65 years and older and 18 (2.6%) patients were aged 75 years and older. No overall differences in safety or effectiveness were observed between these patients and younger adult patients.

Amoxicillin
An analysis of clinical studies of amoxicillin was conducted to determine whether subjects aged 65 and over respond differently from younger subjects. These analyses have not identified differences in responses between the elderly and younger patients, but a greater sensitivity of some older individuals cannot be ruled out.

This drug is known to be substantially excreted by the kidney, and the risk of toxic reactions to this drug may be greater in patients with impaired renal function. Because elderly patients are more likely to have decreased renal function, and it may be useful to monitor renal function.

Clarithromycin:
In a steady-state study in which healthy elderly subjects (65 years to 81 years of age) were given 500 mg of clarithromycin every 12 hours, the maximum serum concentrations and area under the curves of clarithromycin and 14-OH clarithromycin were increased compared to those achieved in healthy young adults. These changes in pharmacokinetics parallel known age-related decreases in renal function. In clinical trials, elderly patients did not have an increased incidence of adverse reactions when compared to younger patients. Elderly patients may be more susceptible to development of torsades de pointes arrhythmias than younger patients [see Warnings and Precautions (5.2)].

Most reports of acute kidney injury with calcium channel blockers metabolized by CYP3A4 (e.g., verapamil, amiodipine, diltiazem, nifedipine) involved elderly patients 65 years of age or older [see Warnings and Precautions (5.2)].

Especially in elderly patients, there have been reports of colchicine toxicity with concomitant use of clarithromycin and colchicine, some of which occurred in patients with renal insufficiency. Deaths have been reported in some patients [see Contraindications (4.2) and Warnings and Precautions (5.2)].

8.6. Renal Impairment
No dosage adjustment of VOQUEZNA TRIPLE PAK or VOQUEZNA DUAL PAK is recommended in patients with mild to moderate renal impairment (eGFR 30 to 89 mL/min). Avoid the use of VOQUEZNA TRIPLE PAK or VOQUEZNA DUAL PAK in patients with severe renal impairment (eGFR < 30 mL/min) [see Clinical Pharmacology (12.3)].

8.7. Hepatic Impairment
No dosage adjustment of VOQUEZNA TRIPLE PAK or VOQUEZNA DUAL PAK is recommended in patients with mild hepatic impairment (Child-Pugh A). Avoid the use of VOQUEZNA TRIPLE PAK or VOQUEZNA DUAL PAK in patients with moderate to severe hepatic impairment (Child-Pugh B or C) [see Clinical Pharmacology (12.3)].

10. OVERDOSAGE
No information is available on accidental overdosage of VOQUEZNA TRIPLE PAK or VOQUEZNA DUAL PAK in humans.

In case of an overdose, patients should contact a physician, poison control center, or emergency room. The available overdosage information for each of the individual components in VOQUEZNA TRIPLE PAK and VOQUEZNA DUAL PAK is summarized below:

Vonoprazan:
There have been no reports of overdose with vonoprazan. In clinical studies, a single dose of 120 mg resulted in no serious adverse reactions. Vonoprazan is not removed from the circulation by hemodialysis. If overdose occurs, treatment should be symptomatic and supportive.

Amoxicillin:
In case of amoxicillin overdosage, discontinue medication, treat symptomatically and institute supportive measures as needed. A prospective study of 51 pediatric patients at a poison-control center suggested that overdosages of less than 250 mg/kg of amoxicillin are not associated with significant clinical symptoms.

Intestinal nephritis resulting in oliguric renal failure has been reported in a small number of patients after overdosage with amoxicillin.

Crystalluria, in some cases leading to renal failure, has also been reported after amoxicillin overdosage in adult and pediatric patients. In case of overdosage, adequate fluid intake and diuresis should be maintained to reduce the risk of amoxicillin crystalluria.

Renal impairment appears to be reversible with cessation of drug administration. High blood levels may occur more readily in patients with impaired renal function because of decreased renal clearance of amoxicillin. Amoxicillin can be removed from circulation by hemodialysis.

Clarithromycin:
Overdosage of clarithromycin can cause gastrointestinal symptoms such as abdominal pain, vomiting, nausea, and diarrhea.

Treat adverse reactions accompanying overdosage by the prompt elimination of unabsorbed drug and supportive measures. As with other macrolides, clarithromycin serum concentrations are not expected to be appreciably affected by hemodialysis or peritoneal dialysis.

11. DESCRIPTION
VOQUEZNA TRIPLE PAK contains vonoprazan tablets, 20 mg, amoxicillin capsules, 500 mg, and clarithromycin tablets, 500 mg for oral administration. VOQUEZNA DUAL PAK contains vonoprazan tablets, 20 mg and amoxicillin capsules, 500 mg for oral administration.

Vonoprazan Tablets
Vonoprazan (as the fumarate), is a potassium-competitive acid blocker (PCAB). Chemically, it is 1H-Pyrrole-3-methanamine, 5-(2-fluorophenyl)-N-methyl-1-(3-pyridinylsulfonfonyl)-2-butenedioate (1:1). Its empirical formula is C_{17}H_{16}FN_{3}O_{2}S•C_{4}H_{4}O_{4} with a molecular weight of 461.5. Vonoprazan has the following structure:

Vonoprazan fumarate is white to nearly white crystals or crystalline powder which melts at 194.8°C. Vonoprazan fumarate is soluble in dimethyl sulfoxide; sparingly soluble in acetone, 1-octanol and acetonitrile.
Each film-coated tablet contains 20 mg of vonoprazan, present as 26.72 mg of vonoprazan fumarate and the following inactive ingredients: croscarmellose sodium, ferric oxide red, fumaric acid, hydroxypropyl cellulose, hypromellose, magnesium stearate, mannitol, microcrystalline cellulose, polyethylene glycol 8000, and titanium dioxide.

Amoxicillin Capsules
Amoxicillin is a penicillin class antibacterial, with a broad spectrum of bactericidal activity against many gram-positive and gram-negative microorganisms. Chemically it is (2S, 5R, 6R)-6-[(R)-2-amino-2-[(p-hydroxyphenyl)acetyl] -3, 3-dimethyl-7-oxo-4-thia-1-azabicyclo [3.2.0]heptan-2-carboxylic acid trihydrate. The molecular formula is C_{16}H_{19}N_{3}O_{5}S • 3H_{2}O and the molecular weight is 419.45. Amoxicillin has the following structure:

Vonoprazan Tablets
Vonoprazan is a semi-synthetic macroide antimicrobial for oral use. Chemically, it is 6-O-methylerythromycin. The molecular formula is C_{38}H_{69}NO_{13}, and the molecular weight is 674.96. Clarithromycin has the following structure:

Each amoxicillin capsule, with yellow opaque cap and body, contains 500 mg amoxicillin as the trihydrate. Inactive ingredients: Capsule shells – ammonium hydroxide, black ferric oxide, gelatin, potassium hydroxide, propylene glycol, shellac, titanium dioxide and yellow ferric oxide; Capsule contents – cellulose microcrystalline and magnesium stearate. Meets USP Dissolution Test 2.

12. CLINICAL PHARMACOLOGY

12.1. Mechanism of Action
Vonoprazan suppresses basal and stimulated gastric acid secretion at the secretory surface of the gastric parietal cell through inhibition of the H^+, K^+-ATPase enzyme system in a noncovalent and reversible manner. Amoxicillin is an antibacterial drug. Clarithromycin is a macrolide antimicrobial drug [see Microbiology (12.4)]. Acid suppression enhances the replication of H. pylori bacteria and the stability and effectiveness of antimicrobials in the treatment of H. pylori infection.

12.2. Pharmacodynamics
Vonoprazan
Antisecretory Activity
Following a single 20 mg dose of vonoprazan, the onset of the antisecretory effect as measured by intragastric pH occurs within 2 to 3 hours. The elevated intragastric pH compared to placebo is maintained for over 24-hours after dosing. The inhibitory effect of vonoprazan on acid secretion increases with repeated daily dosing and antisecretory effect reached steady state by Day 4 with a mean (SD) 24-hour intragastric pH of 6.0 (1.5) following 20 mg once daily dose (not an approved recommended dose). The antisecretory effect of vonoprazan decreases following drug discontinuation although intragastric pH remained elevated compared to placebo for 24 to 48 hours following the dose on Day 7.

Cardiac Electrophysiology
At a dose 6 times the maximum recommended dose, vonoprazan does not prolong the QT interval to any clinically relevant extent.

12.3. Pharmacokinetics
Pharmacokinetic (PK) parameters for vonoprazan 20 mg after a single dose (not an approved recommended dosage) and at steady state following twice daily administration are summarized in Table 6.

<table>
<thead>
<tr>

Cmax = Maximum plasma concentration, AUC0-12h = Area under the plasma concentration-time curve from time 0 to the end of the 12-hour dosing interval; tmax = Time to reach Cmax, t1/2 = Elimination half-life, CL/F = Apparent oral clearance, V/F = Apparent oral volume of distribution.

Vonoprazan
Absorption
Vonoprazan exhibits time independent pharmacokinetics and steady state concentrations are achieved by Day 3 to 4. After multiple doses of vonoprazan ranging from 10 mg (0.5 times the lowest approved recommended single dosage) to 40 mg (2 times the highest approved recommended single dosage) once daily for 7 days in healthy subjects, Cmax and AUC values for vonoprazan increased in an approximately dose-proportional manner.

Steady state mean plasma exposure of vonoprazan following 20 mg twice daily dosing (AUC0-12h = 273 hr*ng/mL, N=10) was approximately 1.8-fold higher compared to Day 1 (AUC0-12h = 155 hr*ng/mL, N=10).

Effect of Food:
In a food effect study in healthy subjects (N=24) receiving vonoprazan 20 mg, a high-fat meal resulted in a 5% increase in Cmax, a 15% increase in AUC, and a delay in median Cmax of 2 hours. These changes are not considered to be clinically significant.

Distribution
Plasma protein binding of vonoprazan ranged from 85 to 88% in healthy subjects and was independent of concentration from 0.1 to 10 mcg/mL.

Elimination
Metabolism:
Vonoprazan is metabolized to inactive metabolites via multiple pathways by a combination of cytochrome P450 (CYP) isoforms (CYP3A4/5, CYP2D6, CYP2C19, CYP2C9 and CYP2D6) along with sulfo- and glucuronosyl-transferases. CYP2C19 polymorphisms have been evaluated in clinical studies and there were no considerable differences in the pharmacokinetics of vonoprazan based on CYP2C19 metabolizer status.

Excretion:
Following oral administration of radiolabeled vonoprazan, approximately 67% of the radiolabeled dose (8% as unchanged vonoprazan) was recovered in urine and 31% (1.4% as unchanged vonoprazan) was recovered in feces.

Specific Populations
Sex, Race or Ethnicity:
There were no clinically significant differences in the pharmacokinetics of vonoprazan based on sex or race/ethnicity.

Patients with Renal Impairment
The pharmacokinetics of vonoprazan administered as a single 20 mg dose in patients with mild (N=8), moderate (N=8) or severe (N=8) renal impairment were compared to those with normal renal function (N=13). Compared to subjects with normal renal function, systemic exposure (AUC∞) was 1.7- 1.3- and 2.4- times greater in patients with mild, moderate, and severe renal impairment, respectively. In subjects requiring dialysis (N=8), AUC∞ estimates were 1.3-fold greater compared to estimates from subjects with normal renal function. Protein binding of vonoprazan is not affected by impaired renal function. In patients requiring dialysis, vonoprazan was present in the dialysate and represented 0.94% of the dose administered.

Patients with Hepatic Impairment
The pharmacokinetics of vonoprazan administered as a single 20 mg dose in patients with mild [Child-Pugh Class A (N=8)], moderate [Child-Pugh Class B (N=8)] or severe [Child-Pugh Class C (N=6)] hepatic impairment were compared to those with normal hepatic function (N=12). Compared to subjects with normal hepatic function, systemic exposure (AUC∞) of vonoprazan was 1.2-, 2.4- and 2.6-times greater in patients with mild, moderate, and severe hepatic impairment, respectively. Protein binding of vonoprazan is not affected by impaired hepatic function.

Drug Interaction Studies
In vitro studies: Cytochrome P450 (CYP450) Enzymes:
In vitro studies have shown that vonoprazan directly and time-dependently inhibits CYP2B6, CYP2C19, and CYP3A4/5.
Transporter Systems:
Vonoprazan inhibits multidrug and toxin extrusion protein 1 (MATE1) and organic cation transporter 1 (OCT1), but only at concentrations higher than clinically relevant.

Clinical Studies:
Combination Therapy with Vonoprazan, Amoxicillin and Clarithromycin:
When vonoprazan 20 mg, amoxicillin 750 mg, and clarithromycin 400 mg were co-administered twice daily for 7 days (N=11), there was no effect on pharmacokinetics of amoxicillin compared to administration of amoxicillin alone. However, vonoprazan Cmax and AUC0-12h increased by 87% and 85%, respectively, and clarithromycin, Cmax and AUC0-12h increased by 64% and 45%, respectively, compared to administration of each component alone.

Effect of Vonoprazan on CYP3A4 Substrates:
When a single oral dose of midazolam 2 mg was administered following vonoprazan 20 mg twice daily for 7 days (N=20), midazolam AUC0 increased 93% compared to administration of midazolam alone.

Effect of CYP3A Inhibitors on Vonoprazan:
When a single 40 mg (2 times the highest approved recommended single dosage) dose of vonoprazan was administered with clarithromycin 500 mg twice daily for 7 days (N=16), vonoprazan AUC0 increased 58% compared to administration of vonoprazan alone.

Model-Informed Approaches:
Effect of CYP3A Inducers on Vonoprazan:
Vonoprazan exposures are predicted to be 80% lower when co-administered with a strong CYP3A4 inducer such as rifampin and 50% lower when co-administered with a moderate CYP3A4 inducer such as efavirenz.

Amoxicillin
Absorption
Amoxicillin is stable in the presence of gastric acid and is rapidly absorbed after oral administration. Orally administered doses of 500-mg amoxicillin capsules result in average peak blood levels 1 to 2 hours after administration in the range of 5.5 mcg/mL to 7.5 mcg/mL, respectively.

Distribution
Amoxicillin diffuses readily into most body tissues and fluids, with the exception of brain and spinal fluid, except when meninges are inflamed. In blood serum, amoxicillin is approximately 20% protein-bound. Following a 1-gram dose and utilizing a special skin window technique to determine levels of the antibacterial, it was noted that therapeutic levels were found in the interstitial fluid.

Metabolism and Excretion
The half-life of amoxicillin is 61.3 minutes. Approximately 60% of an orally administered dose of amoxicillin is excreted in the urine within 6 to 8 hours. Detectable serum levels are observed up to 8 hours after an orally administered dose of amoxicillin. Since most of the amoxicillin is excreted unchanged in the urine, its excretion can be delayed by concurrent administration of probenecid.

Clarithromycin
Absorption
For a single 500 mg dose of clarithromycin, food slightly delays the onset of clarithromycin absorption, increasing the peak time from approximately 2 to 2.5 hours. Food also increases the clarithromycin peak plasma concentration by about 24%, but does not affect the extent of clarithromycin bioavailability. Food does not affect the onset of formation of the active metabolite, 14-OH clarithromycin or its peak plasma concentration but does slightly decrease the extent of metabolite formation, indicated by an 11% decrease in AUC. Therefore, clarithromycin may be given without regard to food. In non-fasting healthy human subjects (males and females), peak plasma concentrations were attained within 2 to 3 hours after oral dosing.

Distribution
Clarithromycin and the 14-OH clarithromycin metabolite distribute readily into body tissues and fluids. There are no data available on cerebrospinal fluid penetration. Because of high intracellular concentrations, tissue concentrations are higher than serum concentrations.

Metabolism and Elimination
Steady-state peak plasma clarithromycin concentrations were attained within 3 days and were 3 mcg/mL to 4 mcg/mL with a 500 mg dose administered every 8 hours to 12 hours. The clearance of clarithromycin was 5 hours with 500 mg administered every 8 hours to 12 hours. The nonlinearity of clarithromycin pharmacokinetics is slight at the recommended doses of 500 mg administered every 8 hours to 12 hours. With a 500 mg every 8 hours to 12 hours dosing, the peak steady-state concentration of 14-OH clarithromycin is slightly higher (up to 1 mcg/mL), and its elimination half-life is about 7 hours to 9 hours. With any of these dosing regimens, the steady-state concentration of this metabolite is generally attained within 3 days to 4 days. After a 500 mg tablet every 12 hours, the urinary excretion of clarithromycin is approximately 40%. The renal clearance of clarithromycin is 5 hours with 500 mg administered every 8 hours to 12 hours. The clearance is relatively independent of the dose size and approximates the normal glomerular filtration rate. The major metabolite found in urine is 14-OH clarithromycin, which accounts for an additional 15% of the dose with a 500 mg tablet administered every 12 hours. Patients with Hepatic Impairment
The steady-state concentrations of clarithromycin in subjects with impaired hepatic function did not differ from those in normal subjects; however, the 14-OH clarithromycin concentrations were lower in the hepatically impaired subjects. The decreased formation of 14-OH clarithromycin was at least partially offset by an increase in renal clearance of clarithromycin in the subjects with impaired hepatic function when compared to healthy subjects.

Patients with Renal Impairment
The pharmacokinetics of clarithromycin were also altered in subjects with impaired renal function.

Drug Interaction Studies
Fluconazole:
Following administration of fluconazole 200 mg daily and clarithromycin 500 mg twice daily to 21 healthy volunteers, the steady-state clarithromycin Cmax and AUC increased 33% and 18%, respectively. Clarithromycin exposures were increased and steady-state concentrations of 14-OH clarithromycin were not significantly affected by concomitant administration of fluconazole.

Colchicine:
When a single dose of colchicine 0.6 mg was administered with clarithromycin 250 mg twice daily for 7 days, the colchicine Cmax increased 197% and the AUC increased 239% compared to administration of colchicine alone.

Atazanavir:
Following administration of clarithromycin (500 mg twice daily) with atazanavir (400 mg once daily), the clarithromycin AUC increased 94%, the 14-OH clarithromycin AUC decreased 70% and the atazanavir AUC increased 28%.

Ritonavir:
Concomitant administration of clarithromycin and ritonavir (N=22) resulted in a 77% increase in clarithromycin AUC and a 100% decrease in the AUC of 14-OH clarithromycin.

Saquinavir:
Following administration of clarithromycin (500 mg twice daily) and saquinavir (soft gelatin capsules, 1200 mg tid) to 12 healthy volunteers, the steady-state saquinavir AUC and Cmax increased 177% and 187% respectively compared to administration of saquinavir alone. Clarithromycin AUC and Cmax increased 45% and 39% respectively, whereas the 14-OH clarithromycin AUC and Cmax decreased 24% and 34% respectively, compared to administration with clarithromycin alone.

Didanosine:
Simultaneous administration of clarithromycin tablets and didanosine to 12 HIV-infected adult patients resulted in no statistically significant change in didanosine pharmacokinetics.

Zidovudine:
Following administration of clarithromycin 500 mg tablets twice daily with zidovudine 100 mg every 4 hours, the steady-state zidovudine AUC decreased 12% compared to administration of zidovudine alone (N=4). Individual values ranged from a decrease of 34% to an increase of 14%. When clarithromycin tablets were administered two to four hours prior to zidovudine, the steady-state zidovudine Cmax increased 100% whereas the AUC was unaffected (N=24).

Omeprazole:
Clarithromycin 500 mg every 8 hours was given in combination with omeprazole 40 mg daily to healthy adult subjects. The steady-state plasma concentrations of omeprazole were increased (Cmax, AUC0-24, and t½ increases of 30%, 89%, and 34%, respectively), by the concomitant administration of clarithromycin.

The plasma levels of clarithromycin and 14-OH clarithromycin were increased by the concomitant administration of omeprazole. For clarithromycin, the mean Cmax was 103% greater, the mean Cmin was 27% greater, and the mean AUC0-24 was 15% greater when clarithromycin was administered with omeprazole than when clarithromycin was administered alone. Similar results were seen for 14-OH clarithromycin, the mean Cmax was 45% greater, the mean Cmin was 57% greater, and the mean AUC0-24 was 45% greater. Clarithromycin concentrations in the gastric tissue and mucus were also increased by concomitant administration of omeprazole.

Table 7: Clarithromycin Tissue Concentrations 2 hours after Dose (mcg/mL)/(mcg/g)

Theophylline:
In two studies in which theophylline was administered with clarithromycin (a theophylline sustained-release formulation was dosed at either 6.5 mg/kg or 12 mg/kg together with 250 or 500 mg q12h clarithromycin), the steady-state levels of Cmax, Cmin, and the AUC of theophylline increased about 20%.

Midazolam:
When a single dose of midazolam was co-administered with clarithromycin tablets (500 mg twice daily for 7 days), midazolam AUC increased 174% after intravenous administration of midazolam and 600% after oral administration.

12.4. Microbiology
Mechanism of Action
Amoxicillin is similar to penicillin in its bactericidal action against susceptible bacteria during the stage of active multiplication. It acts through the inhibition of cell wall biosynthesis that leads to the death of the bacteria.

Clarithromycin exerts its antibacterial activity by binding to the 50S ribosomal subunit of susceptible bacteria resulting in inhibition of protein synthesis.
Resistance to amoxicillin is mediated primarily through enzymes called beta-lactamases that cleave the beta-lactam ring of amoxicillin, rendering it inactive.

The major routes of clarithromycin resistance are modification of the 23S rRNA in the 50S ribosomal subunit to insensitivity or drug efflux pumps. Beta-lactamase production should have no effect on clarithromycin activity.

If *H. pylori* is not eradicated after treatment with clarithromycin-containing combination regimens, patients may develop clarithromycin resistance in *H. pylori* isolates. Therefore, for patients who fail therapy, clarithromycin susceptibility testing should be done, if possible.

**Antimicrobial Activity**

Culture and sensitivity testing of bacteria are not routinely performed to establish the diagnosis of *H. pylori* infection [see Clinical Studies (14)]. The following in vitro data are available, but their clinical significance is unknown. Clarithromycin and amoxicillin are active in vitro against most isolates of *H. pylori*.

**Susceptibility Testing**

For specific information regarding susceptibility test interpretive criteria and associated test methods and quality control standards recognized by FDA for this drug, please see: https://www.fda.gov/STIC.

**Effects on Gastrointestinal Microbial Ecology**

Decreased gastric acidity due to any means, increases gastric counts of bacteria normally present in the gastrointestinal tract. Vonoprazan decreases gastric acidity, VOQUEZNA TRIPLE PAK or VOQUEZNA DUAL PAK may lead to a slightly increased risk of gastrointestinal infections due to pathogens such as *Salmonella* and Campylobacter and, in hospitalized patients, possibly also due to *C. difficile*.

13. NONCLINICAL TOXICOLOGY

No adequate or well-controlled long-term studies have been performed to evaluate the effect of VOQUEZNA TRIPLE PAK and VOQUEZNA DUAL PAK on carcinogenesis, mutagenesis, or impairment of fertility.

**Vonoprazan**

**Carcinogenicity**

In a 24-month carcinogenicity study in mice, vonoprazan at daily oral doses of 6, 20, 60 and 200 mg/kg/day (approximately 0.4, 4, 19, and 93 times the MRHD based on AUC) produced hyperplasia of neuroendocrine cells, gastropathy and benign and/or malignant neuroendocrine cell tumors (carcinoids) in the stomach at all doses in males and at 60 mg/kg/day and greater in females. In liver, increased incidences of hepatocellular adenoma and carcinomas were observed at doses of 20 mg/kg/day and greater in males and 60 mg/kg/day and greater in females. In a 24-month carcinogenicity study in Sprague-Dawley rats, vonoprazan at oral doses of 5, 15, 50 and 150 mg/kg/day (approximately 0.6, 4, 19, and 65 times the MRHD based on AUC) produced benign and/or malignant neuroendocrine cell tumors in the stomach in both male and female rats at doses of 5 mg/kg/day or more. Increased incidence of hepatocellular adenoma and carcinomas and hepatocellular carcinoma in male rat and carcinosarcoma were observed at doses of 50 and 150 mg/kg/day.

In both mice and rats, neuroendocrine tumors in the stomach occurred in association with neuroendocrine hyperplasia and gastropathy in the stomach and increased plasma gastrin concentrations that are consistent with inhibition of gastric acid secretion. Carcinoid tumors have also been observed in rats subjected to fundectomy or long-term treatment with proton pump inhibitors or high doses of H$_2$-receptor antagonists.

**Mutagenesis**

Vonoprazan was negative for mutagenicity in the mouse micronucleus test and was negative in each of these assays.

**Clinical Studies**

**Carcinoid tumors** have also been observed in rats subjected to fundectomy or long-term treatment with proton pump inhibitors or high doses of H$_2$-receptor antagonists. Clarithromycin and amoxicillin are available, but their clinical significance is unknown. Clarithromycin and amoxicillin were weakly positive in the mouse lymphoma assay, but the trend toward increased mutation frequencies in this assay occurred at doses that were also associated with decreased cell survival. Amoxicillin and potassium clavulanate were negative in the mouse micronucleus test and in the dominant lethal assay in mice. Potassium clavulanate alone was tested in the Ames bacterial mutation assay and in the mouse micronucleus test and was negative in each of these assays.

**Impairment of Fertility**

In a multi-generation reproduction study in rats, no impairment of fertility or other adverse reproductive effects were seen at doses up to 500 mg/kg (approximately 1.6 times the human dose in mg/m$^2$).

**Clarithromycin**

**Mutagenesis**

The following *in vitro* mutagenicity tests have been conducted with clarithromycin:

- *Salmonella/Mammalian Microsomes Test*
- *Bacterial Induced Mutation Frequency Test*
- *In Vivo Chromosome Aberration Test*
- *Rat Hepatocyte DNA Synthesis Assay*
- *Mouse Lymphoma Assay*
- *Mouse Dominant Lethal Study*
- *Mouse Micronucleus Test*

All tests had negative results except the *in vitro* chromosome aberration test which was positive in one test and negative in another. In addition, a bacterial reverse-mutation test (Ames test) has been performed on clarithromycin metabolites with negative results.

**Impairment of Fertility**

Fertility and reproduction studies have shown that daily doses of up to 160 mg/kg/day to male and female rats caused no adverse effects on the estrous cycle, fertility, parturition, or number and viability of offspring. Plasma levels in rats after 150 mg/kg/day were twice the human serum levels.

Testicular atrophy occurred in rats at doses 7 times, in dogs at doses 3 times, and in monkeys at doses 8 times greater than the maximum human daily dose (on a BSA comparison).

13.2. Animal Toxicology and/or Pharmacology

**Clarithromycin**

Corneal opacity occurred in dogs at doses 12 times and in monkeys at doses 8 times greater than the maximum human daily dose (on BSA comparisons). Lymphoid depletion occurred in dogs at doses 3 times greater than and in monkeys at doses 2 times greater than the maximum human daily dose (on BSA comparisons).

14. CLINICAL STUDIES

The effectiveness and safety of VOQUEZNA TRIPLE PAK and VOQUEZNA DUAL PAK were evaluated in a randomized, controlled, double-blind triple therapy/open-label dual therapy study conducted in the United States and Europe in treatment-naive *H. pylori*-positive adult patients with at least one clinical condition: dyspepsia lasting at least 2 weeks, functional dyspepsia, recent/new diagnosis of peptic ulcer, peptic ulcer not treated for *H. pylori* infection, or a stable dose of long-term NSAID treatment (NCT 04167670). Patients were randomized 1:1:1 to vonoprazan 20 mg twice daily plus amoxicillin 1,000 mg twice daily plus clarithromycin 500 mg twice daily (VOQUEZNA TRIPLE PAK) or vonoprazan 20 mg twice daily plus amoxicillin 1,000 mg three times daily (VOQUEZNA DUAL PAK) or lansoprazole 30 mg twice daily plus amoxicillin 1,000 mg twice daily plus clarithromycin 500 mg twice daily (LAC) administered for 14 consecutive days.

**H. pylori** infection at baseline was defined as positive by $^{13}$C urea breath test (UBT) and follow-up upper endoscopy (culture or histology). *H. pylori* eradication was confirmed with a negative $^{13}$C UBT test-of-cure at ≥27 days post-therapy. Patients with negative test results were considered treatment successes. Patients who tested positive for *H. pylori* infection and patients with missing results from the test-of-cure visit were considered treatment failures.

VOQUEZNA TRIPLE PAK and VOQUEZNA DUAL PAK were shown to be noninferior to LAC in patients who did not have a clarithromycin or amoxicillin resistant strain of *H. pylori* at baseline. VOQUEZNA TRIPLE PAK and VOQUEZNA DUAL PAK were shown to be superior to LAC in patients who had a clarithromycin resistant strain of *H. pylori* at baseline and in the overall population.

**H. pylori** eradication rates are shown in Table 8 for VOQUEZNA TRIPLE PAK and VOQUEZNA DUAL PAK compared to LAC.

(continued)
VOQUEZNA TRIPLE PAK and VOQUEZNA DUAL PAK are a co-package containing:

- Vonoprazan Tablets, 20 mg: pale red, oval, film-coated tablets debossed V20 on one side and plain on the other side.
- Amoxicillin Capsules, 500 mg: yellow, opaque, hard gelatin capsules imprinted with AMOX 500 on one side and GG 849 on the other side.
- Clarithromycin Tablets, 500 mg: white, oval, film-coated tablets debossed GG C9 on one side and plain on the other side.

VOQUEZNA DUAL PAK is a co-package containing:

- Vonoprazan Tablets, 20 mg: pale red, oval, film-coated tablets debossed V20 on one side and plain on the other side.
- Amoxicillin Capsules, 500 mg: yellow, opaque, hard gelatin capsules imprinted with AMOX 500 on one side and GG 849 on the other side.

VOQUEZNA TRIPLE PAK and VOQUEZNA DUAL PAK are supplied in separate blister cavities within the same blister card. Each unit of use carton (NDC 81520-255-14) contains 56 tablets and 56 capsules divided into 14 daily dose blister cards.

Each daily blister card contains two vonoprazan tablets (20 mg each), four amoxicillin capsules (500 mg each) and two clarithromycin tablets (500 mg each), and indicates which tablets and capsules need to be taken in the morning and evening.

Store between 20°C and 25°C (68°F and 77°F). Brief exposure to 15°C to 30°C (59°F to 86°F) permitted (see USP Controlled Room Temperature).

Take with or without food [see Dosage and Administration (2)].

Missed doses: Advise patients that if a dose of VOQUEZNA TRIPLE PAK or VOQUEZNA DUAL PAK is missed, administer as soon as possible within 4 hours after the missed dose. If more than 4 hours have passed, skip the missed dose and administer the next dose on the regularly scheduled time. It is important for patients to complete the entire course of therapy [see Dosage and Administration (2)].

Counsel patients to continue the full course of VOQUEZNA TRIPLE PAK or VOQUEZNA DUAL PAK regardless of whether or not their symptoms improve. Counsel patients that treatment of H. pylori infection is important due to its association with stomach ulcers, atrophic gastritis and increased risk of gastric cancer.

Antibacterial Resistance

Patients should be counseled that antibacterial drugs including VOQUEZNA TRIPLE PAK or VOQUEZNA DUAL PAK should only be used to treat bacterial infections. They do not treat viral infections (e.g., the common cold). When VOQUEZNA TRIPLE PAK or VOQUEZNA DUAL PAK is prescribed to treat a bacterial infection, patients should be told that although it is common to feel better early in the course of therapy, the medication should be taken for the entire prescribed length, even if symptoms disappear before then. Skipping doses or not completing the full course of therapy may (1) decrease the effectiveness of the immediate treatment and (2) increase the likelihood that bacteria will develop resistance and will not be treatable by VOQUEZNA TRIPLE PAK, VOQUEZNA DUAL PAK or other antibacterial drugs in the future [see Warnings and Precautions (5.1)].

VOQUEZNA TRIPLE PAK and VOQUEZNA DUAL PAK are distributed by Phathom Pharmaceuticals, Inc., Buffalo Grove, IL, 60089, U.S.A.

VOQUEZNA TRIPLE PAK and VOQUEZNA DUAL PAK are a co-package containing:

- Vonoprazan Tablets, 20 mg: pale red, oval, film-coated tablets debossed V20 on one side and plain on the other side.
- Amoxicillin Capsules, 500 mg: yellow, opaque, hard gelatin capsules imprinted with AMOX 500 on one side and GG 849 on the other side.

VOQUEZNA TRIPLE PAK and VOQUEZNA DUAL PAK are supplied in separate blister cavities within the same blister card. Each unit of use carton (NDC 81520-255-14) contains 56 tablets and 56 capsules divided into 14 daily dose blister cards.

Each daily blister card contains two vonoprazan tablets (20 mg each), four amoxicillin capsules (500 mg each) and two clarithromycin tablets (500 mg each), and indicates which tablets and capsules need to be taken in the morning and evening.

Store between 20°C and 25°C (68°F and 77°F). Brief exposure to 15°C to 30°C (59°F to 86°F) permitted (see USP Controlled Room Temperature).

17. PATIENT COUNSELING INFORMATION

Hypersensitivity Reactions

Patients should be aware that VOQUEZNA TRIPLE PAK and VOQUEZNA DUAL PAK can cause allergic reactions in some individuals. Advise the patient to call their healthcare provider immediately if they develop a new rash, urticaria, drug eruptions, swelling of the face, difficulty in breathing or other symptoms of allergic reactions [see Warnings and Precautions (5.1) and Adverse Reactions (6.2)].

Severe Cutaneous Adverse Reactions

Advise patients about the signs and symptoms of serious skin manifestations. Instruct patients to stop taking VOQUEZNA TRIPLE PAK or VOQUEZNA DUAL PAK immediately and promptly report the first signs or symptoms of skin rash, mucosal lesions, or any other sign of hypersensitivity [see Warnings and Precautions (5.1) and Adverse Reactions (6.2)].

Drug Interactions

Advise patients that VOQUEZNA TRIPLE PAK or the individual components of VOQUEZNA TRIPLE PAK may interact with some drugs; therefore, advise patients to report to their healthcare provider the use of any other medications including natural substances and nutritional supplements.

Diarrhea

Advise patients that diarrhea is a common problem caused by antibacterials including amoxicillin and clarithromycin, and it usually ends when the drugs are stopped. However, rarely after receiving treatment with VOQUEZNA TRIPLE PAK or VOQUEZNA DUAL PAK, patients can develop watery and bloody stools (with or without stomach cramps and fever) even as late as 2 or more months after having taken their last dose. If this occurs, instruct patients to contact their healthcare provider as soon as possible [see Warnings and Precautions (5.1)].

Embryo-Fetal Toxicity

Advise pregnant patients and females of reproductive potential that if pregnancy occurs while taking VOQUEZNA TRIPLE PAK, there is a potential risk to the fetus due to the clarithromycin component [see Warnings and Precautions (5.2) and Use in Specific Populations (8.1)].

Advise patients who are exposed to VOQUEZNA TRIPLE PAK or VOQUEZNA DUAL PAK during pregnancy to contact Phathom Pharmaceuticals, Inc. at 1-888-775-PHAT (7428).

Lactation

Advise the lactating women to pump and discard their milk during treatment with VOQUEZNA TRIPLE PAK or VOQUEZNA DUAL PAK and for 2 days after the therapy ends [see Use in Specific Populations (8.2)].

Infertility

Advise males of reproductive potential that VOQUEZNA TRIPLE PAK may impair fertility [see Use in Specific Populations (8.3)].

Potential for Dizziness, Vertigo and Confusion

There are no data on the effect of VOQUEZNA TRIPLE PAK on the ability to drive or use machines. However, counsel patients regarding the potential for dizziness, vertigo, confusion and disorientation, which may occur with clarithromycin, a component of VOQUEZNA TRIPLE PAK. The potential for these adverse reactions should be taken into account before patients drive or use machines.

Important Administration Instructions for VOQUEZNA TRIPLE PAK and VOQUEZNA DUAL PAK

• Take with or without food [see Dosage and Administration (2)].
• Missed doses: Advise patients that if a dose of VOQUEZNA TRIPLE PAK or VOQUEZNA DUAL PAK is missed, administer as soon as possible within 4 hours after the missed dose. If more than 4 hours have passed, skip the missed dose and administer the next dose on the regularly scheduled time. It is important for patients to complete the entire course of therapy [see Dosage and Administration (2)].
• Counsel patients to continue the full course of VOQUEZNA TRIPLE PAK or VOQUEZNA DUAL PAK regardless of whether or not their symptoms improve. Counsel patients that treatment of H. pylori infection is important due to its association with stomach ulcers, atrophic gastritis and increased risk of gastric cancer.
